

Bank Customer Financial Health Analysis : FINHEALTH

A Python-Based Analytical Framework for
Multi-Dimensional Banking Risk Diagnostics

Presented By :

Zulekha Qureshi

Saher Shaikh

Introduction

The banking industry relies heavily on multi-dimensional customer behavioural data to assess creditworthiness, customer retention, and portfolio risk. This project presents the Bank Customer Financial Health Analysis System, a Python-based analytical dashboard designed to evaluate, categorize, and visualize individual and aggregate client financial profiles. By integrating Pandas for structured data handling, NumPy for vectorized mathematical aggregations, and Matplotlib embedded within a native Tkinter desktop interface, the system translates raw tabular metrics into intuitive graphical and diagnostic reports.

Problem Statement

Financial institutions collect vast amounts of granular customer metrics—such as payment records, utilization ratios, and service engagement—that often remain trapped in static, complex spreadsheets.

Banks keep your money safe

Traditional manual reviews are time-consuming, prone to human error, and struggle to accommodate realistic data imperfections like missing records (NaNs) or localized score variances.

Offer services like savings, loans, and payments

Branch managers and credit analysts lack a lightweight, desktop-accessible tool to rapidly compare an individual customer's credit profile against institution-wide benchmarks to make timely lending decisions

Objective

Page
03

Automate Data

Processing:

Seamlessly ingest structured CSV datasets containing customer IDs, names, and key financial health metrics.

Interactive Visualization

Build an interactive graphical user interface (GUI) with embedded Matplotlib visualizations allowing instant side-by-side benchmarking and trend analysis.

Handle Real-World Data Anisotropies

Ensure robust handling of missing values (NaNs) and scoring variances using resilient mathematical aggregation techniques (`np.nanmean`, `np.nanstd`).

Benchmarking & Tier Classification

Implement objective, automated rating bands (from Tier 1 Prime / Grade A down to High Risk / Grade E) based on multi-parameter composite scoring

Methodology

Data Ingestion & Cleaning (Pandas):

- Reads tabular data from CSV files and verifies schema integrity (verifying customer identifiers and scoring dimensions).
- Detects and isolates null or incomplete records across evaluation parameters.

Vectorized Mathematical Computation (NumPy):

- Converts metric slices into high-performance numerical arrays for matrix computations.
- Calculates parameter-level means, standard deviations, and composite weighted averages using NaN-aware vector operations.
- Uses conditional tier mapping (`np.select` / `np.histogram`) to segment score populations into discrete credit health categories.

Analytical Visualization (Matplotlib):

- Generates error-bar benchmarks, categorical rating histograms, dual-bar comparative charts, and line-based score trajectories.
- Formats charts with high-contrast, clean palettes optimized for executive reporting.

Interactive Desktop GUI (Tkinter & FigureCanvasTkAgg):

- Couples dynamic radio buttons, dropdown selectors, and sub-metric filters with callback handlers.
- Renders dynamic Matplotlib canvas elements directly inside a structured responsive desktop container.

System Architecture & GUI Implementation

This project is a desktop software application built with Python that serves as a financial health dashboard for banks. Instead of reading through hundreds of raw numbers in an Excel spreadsheet, a bank manager can load customer records and instantly view easy-to-read charts, scores, and credit ratings right inside a clean window. In simple terms, it takes raw bank numbers—like bill payments, savings habits, and loan history—and turns them into visual graphs and risk ratings.

Why It Is Useful?

- **Saves Time:** Evaluating a customer's entire financial history takes seconds instead of hours of manual calculation.
- **Instant Comparison:** It immediately shows whether a customer performs better or worse than the bank's average across every financial area.
- **Finds Hidden Risks:** Instead of only checking a single total score, it points out a customer's specific weak spots (for example, someone might have a high income but a poor loan repayment record).

Data Ingestion & Initial Dashboard View

This interface represents the initial operational phase of the system, where a clean dual-panel layout guides the user to load structured records before analysis begins. The primary dashboard initiates in an intuitive empty state—prompting the user to select an analytical mode—while the left navigation panel provides seamless data ingestion through a native file explorer dialog (filedialog) to import target CSV datasets without exposing technical file-handling paths to non-technical users.

Granular Customer Diagnostics & KPI Profile View

This interface demonstrates the drill-down capabilities of the dashboard, where selecting an individual client from the dynamic combobox generates an automated executive financial profile.

1. This bar chart illustrates the macro-level operational health of the institution by plotting the average score across all seven evaluated financial parameters alongside their standard deviations (np.nanstd).
2. A dashed reference line at 71.7 establishes the overall institutional baseline, showing that portfolio-wide metrics remain tightly clustered between 70.2 (Loan Repayment) and 72.6 (Digital Banking).

1. This categorical histogram visualizes the distribution of all evaluated metric scores across five distinct creditworthiness tiers, ranging from Very Poor (<60) to Excellent (90–100).
2. The portfolio displays a central tendency, with the largest concentration falling into the Fair tier (904 evaluations, 25.8%) and Poor tier (840 evaluations, 24.0%), while prime scores in the Excellent tier account for 12.3% (429 evaluations).

- 1. This side-by-side dual-bar chart compares an individual client's metrics (Yash Mishra, ID: 1179) against the bank-wide baseline for each financial dimension.
- 2. The visualization highlights clear divergences: Yash significantly outperforms the bank average in Payment History (86 vs. ~72) and Customer Service (84 vs. ~72), but falls below the baseline in Savings Habit (60 vs. ~71) and Investment Activity (56 vs. ~72).

- 1. This trajectory line chart plots Yash Mishra's score across all parameters against two critical risk thresholds: the Good Standing benchmark (80) and the Risk Cutoff line (60).
- 2. Based on an overall composite mean, the customer is assigned a Tier 3 Moderate rating (Credit Rating: C), with the curve pinpointing Investment Activity (56) as a high-risk outlier below the safety threshold.

Future Scope

1. **Add AI & Smart Predictions:** Teach the system to predict whether a customer might fail to repay a loan or leave the bank in the future, instead of only checking past scores.
2. **Smarter Handling of Missing Data:** Use smart mathematical formulas to estimate and fill in blank or missing customer information more accurately.
3. **Direct Live Database Connection:** Connect the tool directly to live bank databases so scores update automatically every day, without needing to upload CSV files by hand.
4. **Custom Score Importance:** Allow bank managers to decide which habits matter most (for example, giving more importance to on-time loan payments than digital banking use).
5. **One-Click PDF Reports:** Add a simple button that creates and downloads a printable summary report or certificate for any selected customer.
6. **Make It a Web App:** Turn this computer software into a website so branch staff can open it inside Google Chrome or Edge on any device without installing Python.

Conclusion

The Bank Customer Financial Health Analysis System demonstrates how standard data science libraries—Pandas, NumPy, and Matplotlib—can be combined with Tkinter to transform dense, multi-parameter banking spreadsheets into an intuitive, real-time diagnostic dashboard.

By incorporating NaN-aware array computations and vectorized aggregations, the system processes incomplete customer records without mathematical bias or system failures, establishing a portfolio benchmark across all seven behavioral dimensions. The platform segments credit risk across five tiers and allows risk officers to move from bank-wide performance metrics to granular, single-customer profiles with dual-bar baselines and trajectory charts. Ultimately, this desktop tool provides a scalable, zero-cloud-dependency solution that reduces assessment time, highlights behavioral vulnerabilities, and delivers clear decision support for modern credit underwriting

THANK
YOU!
